

DOCUMENTATION

Getting the most out of Solace

Solace is the AI audit engine that powers Cygent's deep security audits.

The quality of Solace's audit output scales directly with the context provided. Prepare your repository with these files before running an audit to maximise signal accuracy and minimise false positives.

RECOMMENDED FILES

Best practice

01

scope.md

Place in the base directory. List all files in scope for the audit. Removes guesswork and eliminates scoping errors before the audit begins.

Best practice

02

/docs or /specs folder

All protocol documentation and specifications in markdown format. The more complete this is, the better Solace understands the intended behaviour of the system.

Recommended

03

invariants.md

Either a single invariants.md or per-contract spec files defining the important properties for each contract. Solace will parse these and actively try to break them during analysis.

Recommended

04

trust_model.md

List every role in the system. Specify whether each is trusted, protocol-controlled, or a third-party permissioned role, and what it should not be able to do if compromised. Critical for RBAC protocols.

Recommended

05

known-issues.md

Document design decision trade-offs that could look like bugs but are intentional and accepted. Significantly improves signal-to-noise ratio and reduces false positives in the final report.

If applicable

06

Cross-chain context

For protocols with external integrations or cross-chain interactions, provide documentation on external contracts, bridges, and integration behaviour. Solace will attempt to fetch on-chain source code automatically, but supplementary documentation significantly reduces the information gap.

DOCUMENTATION HYGIENE

Best practice

07

Keep docs clean and current

Only include the latest version of all documentation in the repository submitted for audit. Mixed or conflicting doc versions, older drafts, outdated specs, and superseded architecture notes significantly reduce Solace's ability to determine which source is authoritative during the recon phase. This is especially common in repos where AI-generated docs have been iterated on over time.

- Store all documentation in a single /docs folder at the repo root
- Remove or archive any outdated, superseded, or conflicting versions before running an audit
- Do not leave historical drafts alongside the latest specs. Only the current, accurate version should be present
